

SalesSig – Prototype Documentation

What is SalesSig?

SalesSig is a sales signal monitoring tool built for founders and small teams. It watches communities like Hacker News, Dev.to, and Product Hunt for posts that match your product's target audience. When it finds a relevant post, it uses AI to generate a helpful, non-spammy reply that you can review and post manually.

Technologies Used

The project is a Python Flask web application. It uses Flask as the backend web framework and serves two HTML frontend pages. The AI functionality is powered by Google Gemini (gemini-2.5-flash model) through the google-genai Python library. It connects to two external APIs: the Hacker News Algolia search API (free, no key needed), the Dev.to API (uses an API key), Environment variables are managed using python-dotenv and stored in a .env file.

File Structure

app.py is the main Flask application. It defines all the API routes and manages in-memory state for signals, replies, pipeline, and activity. agent.py contains the logic for scraping the three platforms and calling Gemini to generate replies and score ICP (Ideal Customer Profile) fit. The templates folder contains dashboard.html and index.html which are the two pages served to the user. The .env file holds all the API keys.

How the Workflow Works

Step 1 – Setup. The user opens the app at <http://127.0.0.1:5000> and fills in their product details: name, description, ideal customer, the problem it solves, and website URL. This is submitted to the /api/setup endpoint which saves the product info in memory.

Step 2 – Scan

. The user clicks Scan on the dashboard. This hits the /api/scan endpoint which calls agent.py to extract keywords from the product description, then searches Hacker News, Dev.to. All found posts are stored as signals with a unique ID, timestamp, and status of new.

Step 3 – Review Signals

. The dashboard polls /api/signals every 5 seconds and displays found posts with their platform, title, snippet, and engagement score.

Step 4 – Generate Reply.

The user clicks to generate a reply for a signal. This calls /api/reply which sends the signal content and product info to Gemini. Gemini writes a genuine-sounding 3–5 sentence reply mentioning the product naturally. The reply is saved with a status of draft.

Step 5 – ICP Scoring.

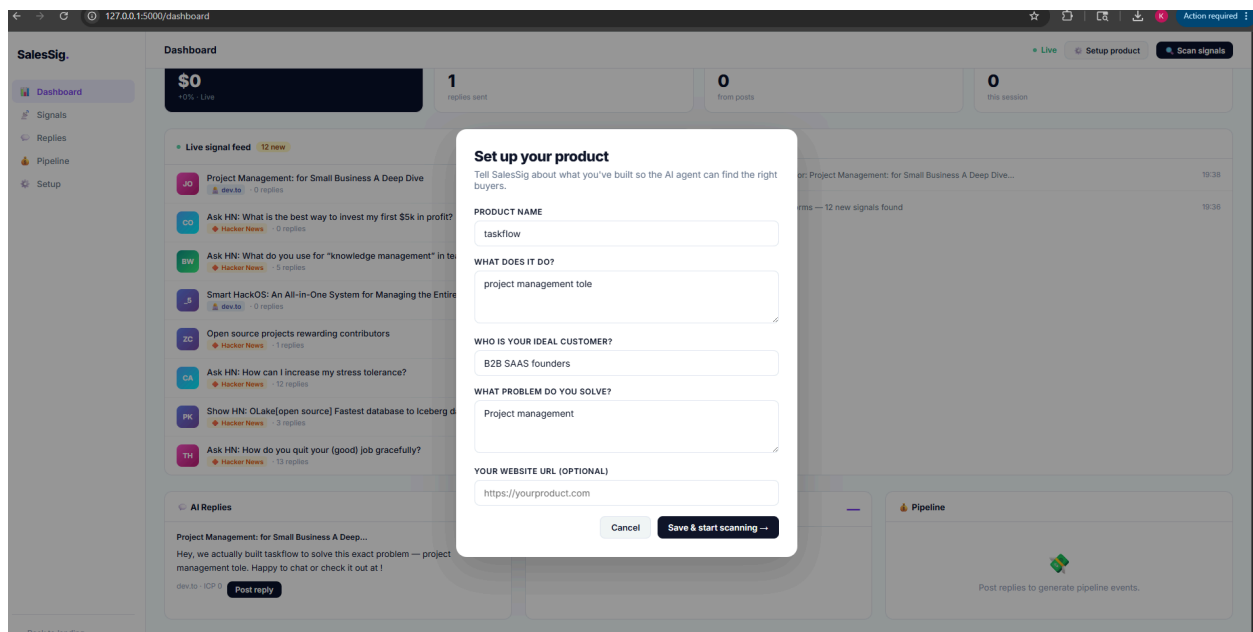

The user can request an ICP analysis. This calls `/api/analyze_icp` and Gemini scores the signal on five axes: industry fit, company size, tech stack match, buyer intent, and region. It returns an overall score and a verdict of Strong, Good, or Weak match.

What Happens When You Click Post?

When you click the Post button on a draft reply, the app calls the `/api/post_reply` endpoint. This endpoint marks the reply status as posted in memory and logs an activity entry saying the reply was posted successfully. However, it does not actually post anything to Hacker News, [Dev.to](https://dev.to). The comment in the source code explicitly says simulated.

After marking it posted, the app randomly simulates a lead attribution event. With roughly 60% probability it adds a fake company (like Acme Corp or Globex) to the pipeline and increments the stats counters for customers attributed, customers won, and clicks tracked. This is entirely made-up demo data to show what the pipeline section would look like.

So to be clear: clicking Post only updates the local in-memory state of the app. You would still need to go to the actual platform, find the post, and manually paste and submit the reply yourself.

» Agentic marketing

B2B growth, on autopilot.

SalesSig is agentic marketing for B2B founders. It finds where your B2B buyers already hang out, posts for you, and shows you which conversations actually turn into paying customers.
